

# Talk: PACT V - Khovanov homology of slice disks

September 9, 2021 1:35 PM

1

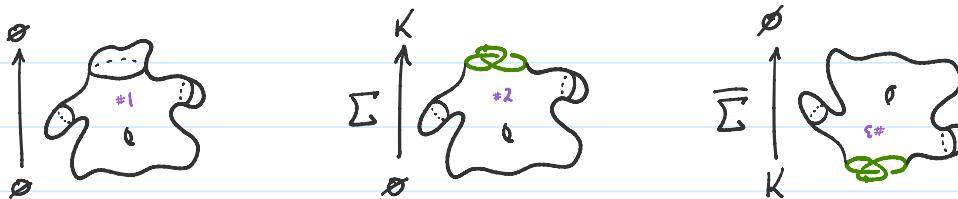

## I MOTIVATION

## II KHOVANOV HOMOLOGY OF LINKS III AND SURFACES

## IV KHOVANOV-JACOBSSON CLASSES

## V KHOVANOV HOMOLOGY OF SLICE DISKS

We consider 3 cases:

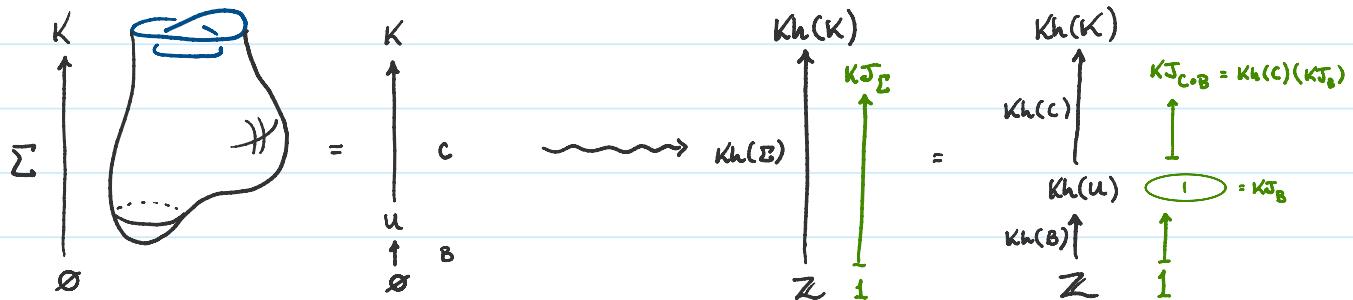

Aside: Link cobordisms can be composed! Given  $X: L_0 \rightarrow L_1$  and  $Y: L_1 \rightarrow L_2$ , we can form  $Y \circ X: L_0 \rightarrow L_2$  by stacking  $Y$  onto  $X$ .

Note: Case #1 looks a lot like #2 with something stacked on it!

## THOUGHT EXPERIMENT

Suppose  $\Sigma: \emptyset \rightarrow K$  is a ribbon disk. Then  $\Sigma = C \circ B$ , where  $C: u \rightarrow K$  is a ribbon-concordance and  $B: \emptyset \rightarrow u$  is a Morse birth.

Recall ribbon-concordances induce injections and  $\text{KJ}_B$  is a nontrivial class

in  $\text{Kh}^{0,0}(u)$  because it is not a boundary (note  $\text{Kh}^{0,0}(u)$  is trivial).

Thus  $\text{KJ}_\Sigma - \text{KJ}_{C \circ B}$  is nontrivial!

2

- ! If we find a slice disk  $D: \emptyset \rightarrow K$  with trivial  $KJ_D$  then  $K$  cannot be a ribbon knot (disproving the Slice-Ribbon conjecture!)

Thm ★ (Swann '10) For a link cob.  $\Sigma: \emptyset \rightarrow K$  with genus  $g(\Sigma) \leq 1$ ,

if  $K$  is slice, then  $KJ_\Sigma$  is nontrivial.

$g=0 \Rightarrow$  slice disks also have nontrivial  $KJ$ -classes

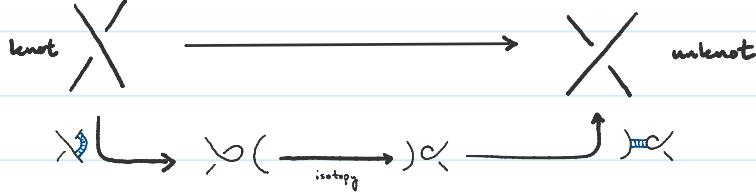

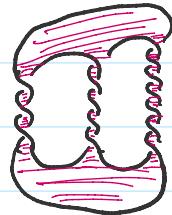

$g=1 \Rightarrow$   $KJ$ -classes can obstruct sliceness (of knots w/ 4-ball genus at most 1)

Thm (Swann '10) Odd 3-stranded pretzel knots  $P(a,b,c)$  with  $a,b,c$  all positive bound genus 1

Seifert surfaces with trivial  $KJ$ -classes, and thus, are not slice.

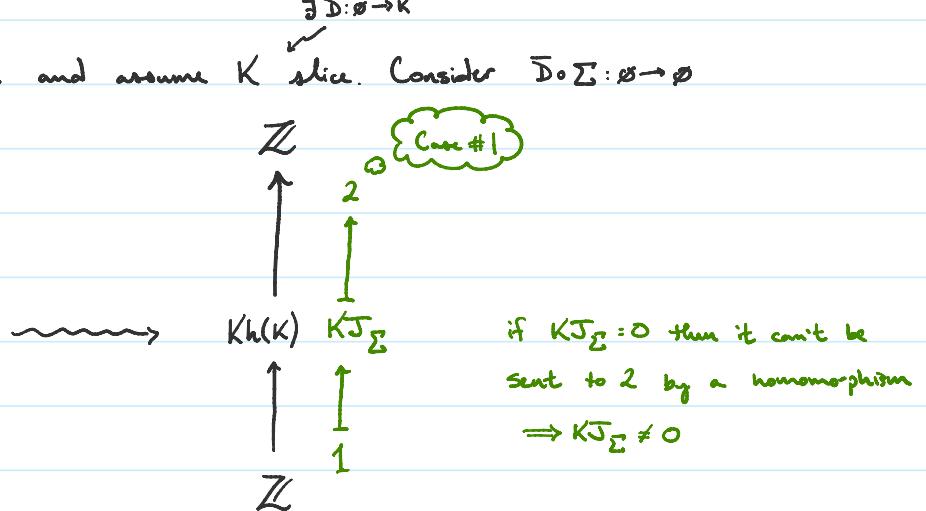

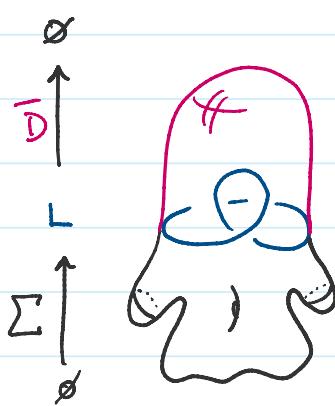

NOTE: Knots w/ unknotting number 1 bound genus 1 surfaces and are thus good candidates

$P(3,5,7)$

Ex's Conway knot, Whitehead double

Proof of ★ Let  $g(\Sigma)=1$  and assume  $K$  slice. Consider  $\overline{D} \circ \Sigma: \emptyset \rightarrow \emptyset$

For  $g(\Sigma) = 0$  consider  $(\bar{D} \# T^2) \circ D : \emptyset \rightarrow \emptyset$

3

Case #3 joint w/ Kyle Hayden (HC '13)

IDEA Reverse the movie of  $\Sigma : \emptyset \rightarrow K$  to get a movie for  $\bar{\Sigma} : K \rightarrow \emptyset$ .

Choose some  $\phi \in \text{Kh}(K)$  and consider

$$\Sigma_\phi := |\text{Kh}(\bar{\Sigma})(\phi)| \in \mathbb{Z}$$

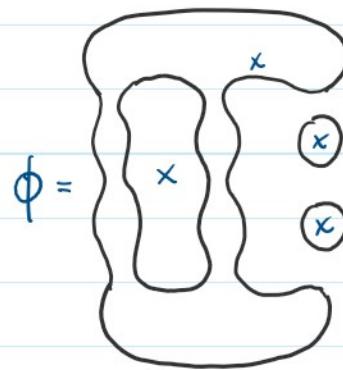

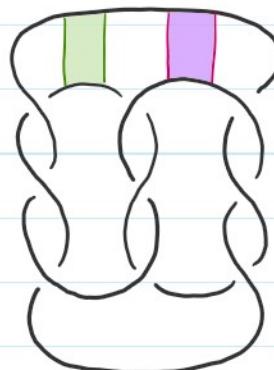

which is an invariant of the boundary-preserving class of  $\Sigma$  (or  $\bar{\Sigma}$ )

Fixes many "complexity" issues:

- by choosing  $\phi \in \text{Kh}(K)$  we can control how awful calculations become
- can easily compare  $\Sigma_\phi$ 's (integers)

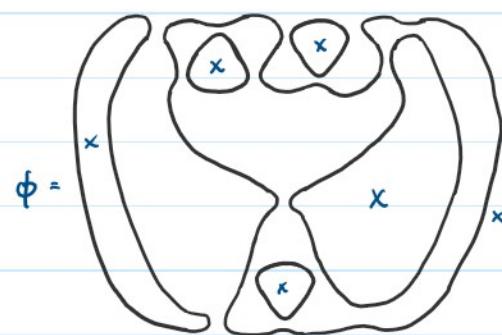

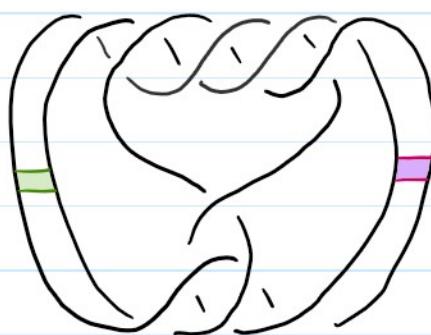

Then The slice disks  $D_l$  and  $D_r$ , given by band moves  $l$  and  $r$  on the given knot  $K$ , are distinguished by the given class  $\phi \in \text{Kh}(K)$ ,  $D_{l,\phi} \neq D_{r,\phi}$

a.  $K = 9_{46}$

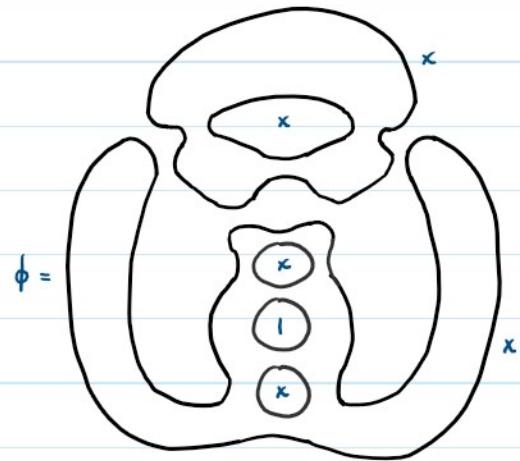

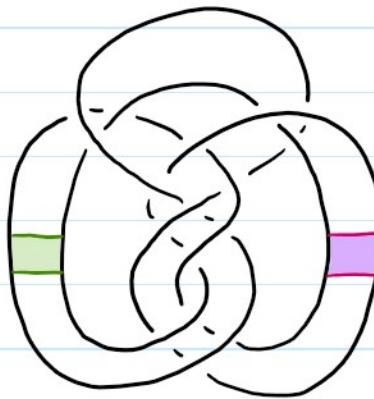

4

$$\textcircled{b} \quad K = 15_{n_{103488}}$$

$$\textcircled{c} \quad J = 17_{n_{34}}$$

FACT: The slices  $D_\epsilon$  and  $D_{-\epsilon}$  for  $J$  are continuously isotopic rel  $J$

Since they are not smoothly isotopic rel  $J$ , we say they are exotic disks.

↳ Can be generalized to inf many exs with any genus that are not ambiently isotopic

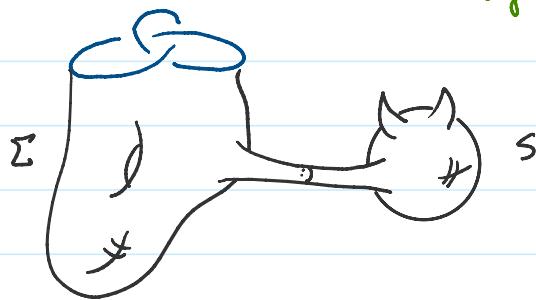

↳ w/ pairs of bands

↳ extended by a concordance to (amphichiral) knot  
with trivial symmetry group

(5)

CHEATING Given a link cob.  $\Sigma': L_0 \rightarrow L_1$ , and a knotted 2-sphere  $S$ ,  
the surfaces  $\Sigma$  and  $\Sigma \# S$  are (generally) not isotopic

↑  
say  $\Sigma$  is locally knotted

There (Hayden-S., Swann)  $\xrightarrow{L_0 \#}$  The cobordism maps on Khov. hom. do not detect  
local knotting:  $\text{Kh}(\Sigma) = \pm \text{Kh}(\Sigma \# S)$
